TITLE: Gamma-radiation absorption in macrosystems

PERIODICAL: Referativnyy zhurnal. Khimiya, no. 22, 1961, 37, abstract  
22B254 (Tr. Tashkentsk. konferentsii po mirn. ispol'zovaniyu  
atomn. energii. Tashkent, AN UzSSR, v. 2, 1960, 123-132)

TEXT: The gamma radiation energy absorbed by an object is determined as the difference between the  $\gamma$ -radiation energy flux from the source and  $\gamma$ -energy flux passing through the object's surface. An accumulation factor for the energy flux and a useful coefficient of the source with respect to  $\gamma$ -radiation are defined. The energy from  $\text{Co}^{60}$  ( $\sim 2$  g-equ. Ra) absorbed by the object was measured by means of a chemical dosimeter - a ferrosulfate solution filled into volumes of various shapes. The  $\gamma$ -radiation energy flux was also measured by the ferrosulfate method. It was shown that if the source was placed in the center of a cylinder the absorbed energy is twice as high as that when the source is located at the

Gamma-radiation absorption ...

bottom plane of a cylinder which is half as high. The accumulation factors were calculated by comparing the experimental and theoretical results without taking multiple scattering into account.  $\gamma$ -radiation absorption in volumes of complex shape was studied at various positions of the sources. TITLE: Passage of gamma radiation through seams of assembled concrete shields

SOURCE: Atomnaya energiya, v. 20, no. 5, 1966, 426-427

TOPIC TAGS: reactor shielding, gamma radiation, radiation dosimetry/SBM-10  
gamma counter

ABSTRACT: This is an abstract of article no. 81/3550, submitted to the editor and filed, but not published in full. In view of lack of data on the shielding properties of assembled shields, and in view of the lack of well founded methods of calculating the passage of gamma rays through screens, the authors propose as a basic criterion for estimating the shielding efficiency a coefficient equal to the ratio of the integral or maximal dose intensities behind the assembled screen and an equivalent monolithic shield. An expression is proposed for this coefficient and its validity was tested with a cobalt source of activity 500 gram equivalent of radium in two source geometries (collimated and isotropic source. The

counter used (SBM-10) had a much smaller diameter (0.6 cm) than the width of the seam, so that it could be regarded as pointlike. The experiments have demonstrated that the use of assembled shields does not lead to an appreciable local rise of the dose intensity behind the screen. The passage of the gamma radiation through the seams is described sufficiently well by the proposed formula. The effect of the seam can be compensated by increasing the shield thickness or by decreasing the seam length through the use of an assembly consisting of several layers. Orig. art. has: 2 formulas.

TITLE: A "Radiating" Nuclear Reactor 19

PERIODICAL: Atomnaya energiya, 1960, Vol. 9, No. 2, pp. 132-133

TEXT: The authors used the term "radiating" reactor for such reactors whose coolant- or fuel circuit may be used as gamma-radiation source. A disadvantage of reactors with circulating fuel is the occurrence of retarded neutrons and comparatively low specific radiation power; reactors with sodium coolants also have a low specific radiation power, and a further disadvantage is the high chemical activity of sodium. A uranium reactor with a graphite (or beryllium) moderator, enriched to 10 - 25%, would not have these disadvantages. A liquid indium-gallium alloy might be used as coolant, which would, at the same time, be a carrier of the gamma activity. The main radiation power is supplied by indium, and gallium serves the purpose of reducing the melting point of the alloy (at 16.5 at% In it is about 16°C). The specific radiation power of this alloy in a flux of  $10^{13} \text{n/cm}^2 \cdot \text{sec}$  is 1,200 w/l. The authors theoretically investigated such a reactor already in an earlier paper (Ref. 1), and carried out estimations of the neutron-

and thermal equilibrium and the radiation power of the circuit. Thus, 40 l of a coolant of the aforementioned composition with a temperature of 50 - 300°C suffice for a heterogeneous uranium-graphite reactor with a 20% enrichment and a heat output of 20 Mw. The optimum radiation power of an ideal group is ~40 kw (equivalent to  $4 \cdot 10^6$  g Ra). The radiation power of such a reactor might, for instance, be used for the polymerization of 4,400 tons of polyethylene per annum; the costs of such a production would amount to 200 million rubles. The maximum gamma-radiation energy is 1.5% of the fission energy (in the case of an ideal loop). The authors finally thank Academician A. P. Aleksandrov, V. L. Karpov, S. M. Feynberg, Yu. F. Chernilin, and Ye. P. Kunesin for discussions. There are 9 references: 3 Soviet, 5 US, and 1 Canadian.

## BESTRAHLUNGSKREISLÄUFE MIT EINEM KERNREAKTOR ALS STRAHLENQUELLE.)

Praktische Bedeutung kommt nur dem Teil der Kurve zu, der die Widerstandsfähigkeit und die Form eines Stahlrohrs auf den Wasserdruckbeanspruch bestimmt. Letztere trifft nicht auf Stahl mit dem Stahlrohr aus, das die Fließgrenze erreicht hat. Wiederholung und der Widerstandsfaktor, die Kurve charakterisiert somit das Kalibrierungsvermögen der Versuchsanordnung.

## Zusammenfassung

Pump mit einer Sauerstoffzufuhr von 3,1 l/min und bei der für die Arbeit eines Verletzten im Hinterland benötigten Sauerstoffzufuhr von 1,6 l/min. Eine entsprechende Versorgung ist nicht möglich. Die Pumpe kann nur auf dem Rücken des Patienten montiert werden, während die Pumpe selbst auf dem Rücken des Verletzten montiert ist. Ein weiterer Nachteil ist die Tatsache, dass die Pumpe nicht leicht zu reinigen ist.

TITLE: The Effective Utilization of Fuel Elements of Nuclear Reactors  
as Sources of  $\gamma$ -Radiation in Radiochemical Equipment

PERIODICAL: Doklady Akademii nauk SSSR, 1961, Vol. 136, No. 3,  
pp. 671-674

TEXT: The authors made a theoretical study to determine the possibilities of utilizing industrial atomic waste, especially nuclear reactor fuel elements as sources of  $\gamma$ -radiation in equipment used for radiochemical processes. The data of Refs. 5-9 on the radiation intensity of fission fragment mixtures ( $\gamma$  or  $\beta+\gamma$ ) offer no possibilities of calculating the efficiency of various applicabilities of fuel elements. For this, it would be necessary to know the average specific  $\gamma$ -radiation power  $K$  released in the equipment during the whole operation period of the reactor body:

$$\bar{P} = \sum_{i=1}^n E_i^y / K = \bar{P} (t_p, t_y, t_B, n) (I), \text{ where } \sum_{i=1}^n E_i^y \text{ denotes the}$$

Card 1/4

The Effective Utilization of Fuel Elements  
of Nuclear Reactors as Sources of  
 $\gamma$ -Radiation in Radiochemical Equipment

S/020/61/136/003/026/027  
B016/B052

$\gamma$ -radiation power of the fragments released in the equipment during the operation of the fuel element in cycle  $i$ ,  $t_p$  and  $t_y$  the operation period of the fuel element in the reactor and the equipment, respectively, during one cycle;  $t_B = t_p + t_y$ ;  $t_p$  and  $t_y$  denote the periods necessary for the transport of one fuel element from the reactor to the equipment and vice versa;  $n$  denotes the number of cycles. The authors also introduce a parameter, namely the coefficient of the loss of the  $\gamma$ -radiation energy of fission fragments in the equipment:

$$\eta_\gamma = \sum_{i=1}^n E_i^y / \sum_{i=1}^n E_i^B = (t_p, t_y, t_B, n) \quad (2), \text{ where } E_i^B \text{ denotes the}$$

$\gamma$ -radiation energy of the fission fragments released in the whole equipment body in cycle  $i$ . In Ref. 10 it is proven that during the circulation of fuel elements not completely burned out,  $P$  can be increased by a multiple as compared to the burned out fuel elements used

Card 2/4

only once. The maximum value of  $\bar{P}$  is reached at  $t_y = t_p$ . In some cases, however, the ratio  $t_y > t_p$  may be more suitable. From their calculations, the authors conclude that  $t_p$  should be as small as possible for the ranges of the values  $t_p$ ,  $t_y/t_p$ ,  $t_B/t_p$ . According to the authors, the results obtained in the present paper may be used for the calculation of any radiation equipment in which fuel elements of nuclear reactors operated with thermal neutrons, are used as source of  $\gamma$ -radiation. The authors thank M. G. Yefimov for discussing the paper, and S. I. Berestetskaya for drawing the diagrams. There are 3 figures, 4 tables, and 12 references: 7 Soviet, 1 US, 1 British, and 2 Polish.

Candidate of Physics and Mathematics; Ya. Kh. Turakulov, Doctor of Biological Sciences. Ed.: R. I. Khamidov; Tech. Ed.: A. G. Babakhanova.

PURPOSE : The publication is intended for scientific workers and specialists employed in enterprises where radioactive isotopes and nuclear radiation are used for research in chemical, geological, and technological fields.

COVERAGE: This collection of 133 articles represents the second volume of the Transactions of the Tashkent Conference on the Peaceful Uses of Atomic Energy. The individual articles deal with a wide range of problems in the field of nuclear radiation, including: production and chemical analysis of radioactive isotopes; investigation of the kinetics of chemical reactions by means of isotopes; application of spectral analysis for the manufacturing of radioactive preparations; radioactive methods for determining the content of elements in the rocks; and an analysis of methods for obtaining pure substances. Certain

TITLE: Radiation thermal cracking of gas-oil from Romashki petroleum

PERIODICAL: Izvestiya vysshikh uchebnykh zavodov. Naft' i gaz, no. 12,  
1961, 99 - 101

TEXT: The effect of gamma radiation on the cracking of gas-oil, F. B. P.  
300 - 345°C, from Romashki petroleum has been studied. For the experiments  
a gamma unit, K-18000 (K-18000), was used, and the dose was maintained  
constant at 100 r/sec.; the temperatures were 400 and 425°C, the maximum  
dose was 5 Mr, and the experiment took 14 hr. It was established that

60 Co gamma rays intensifies the cracking process considerably, and that the  
feed is converted twice as rapidly as in thermal cracking. The yield of  
the lightest fraction, I. B. P 200°C, exceeds that of all other fractions ✓  
from a dose of 3.5 Mr upward and reaches 30 to 35% of the feed at a dose  
of 5 Mr. However, the olefin content of this fraction is lower than that  
of the corresponding fraction in thermal cracking. There are 6 figures and

TITLE: Absorption of neutrons from a fast-neutron source by  
cadmium and indium plates in water

PERIODICAL: Atomnaya energiya, v. 13, no. 3, 1962, 266-269

TEXT: More precise calculations are given in two-group approximation, related to earlier estimates of the activation of the indium-gallium radiation loop in the MPT(IRT) reactor, (Ref. 1: A. Kh. Breger et al, International Conference on Powerful Radiation Sources, Warsaw, 1959; Paper no. 80). The model considered is much simplified. Assume an infinitely large plane isotropic fast-neutron source of uniform density situated at  $x = 0$  in an infinite uniform homogeneous medium. Parallel to this at a distance  $f$  assume a plate which is penetrable to fast neutrons but black to slow neutrons. The probability  $Q$  of a neutron being absorbed in the plate is calculated. The formula obtained for  $Q$  was verified by carrying out measurements in a trough containing an aqueous solution of 12%  $MnSO_4$ , using  $Ra-\alpha$ -Be or  $Po-\alpha$ -Be in a steel cylinder filled with

Card 1/2

B102/B104

Absorption of neutrons from ...

paraffin as a neutron source and with absorbing plates made from 1 mm Cd sheets either alone or plus 0.15 mm In foil. Q was calculated from the saturation activity induced in the Mn as measured with and without the absorbing plates. The  $Q(\xi)$  lines plotted experimentally were compared with those calculated. In both cases, these lines slope gradually downward; the theoretical lines rather less steeply than the experimental so that they intersect at  $7 < \xi < 8$  cm. The principal parameters of the fast and slow neutron groups are given. The deviation of the two  $Q(\xi)$  curves is due to the ideality of the model. The results are compared with those obtained by another method and the specific  $\gamma$ -dose rate of the irradiator of the PK-1 (RK-1) reactor loop is estimated numerically. The results coincide with the estimates in Ref. 1. There is 1 figure.

TITLE: The Absorption of <sup>19</sup>Gamma-emission in Macrosystems From a Point Source

PERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol. 131, №. 6, pp. 1308 - 1311

TEXT: The authors define the absorbed power of  $\gamma$ -emission with  $Q_a = \Phi_0 - (\Phi_{surf} + \Phi_{scatt})$ , where  $\Phi_0$  is the total power of the energy flux of the  $\gamma$ -emission of the source, and  $\Phi_{surf}$  - the power of the flux leaving the absorbing body, and  $\Phi_{scatt}$  - the power of the scattered flux. The factor of the accumulation  $B_\Phi$  of the integral energy flux of the  $\gamma$ -emission is defined by  $B_\Phi = 1 + \Phi_{scatt}/\Phi_{surf}$  and by the notations  $Q_a/\Phi_0 = \eta$ ;  $\Phi_{surf}/\Phi_0 = \varphi_{surf}$  is obtained for the efficiency  $\eta = 1 - B_\Phi \varphi_{surf}$ . For a spherical absorbing body in the center of which the source is located,  $\eta$  may easily be written down. For a cylindrical body (Fig. 1) the

authors derive formula (4) for  $\varphi_{\text{surf}}$ . Determination of  $B_\Phi$  was carried out in a test series, in which dosimetric solutions were located in cylindrical containers with different radii. In a copper tube, which was fitted to the cylinder axis, the  $\gamma$ -source could be moved from without. Measured values for five different cylinder diameters within the range of from 3 to 12 cm are graphically represented in Fig. 3. It is found that the relation  $B_\Phi = F(h/r, \mu r)$  holds, where  $h$  denotes the height of the cylinder calculated from the source,  $r$  - the radius of the cylinder, and  $\mu$  the coefficient of the linear weakening of the  $\gamma$ -emission in the substance (Fig. 3). In this way it was possible to determine not only the amount of the absorbed energy, but also the above introduced factor of the accumulation of the integral energy flux. This factor may be used also in investigations of the absorbed energy which are carried out with other configurations of the source or of the absorbing object. The authors thank N. A. Krasnoshchekova and Ye. D. Kalmykova for their help in performing this work. There are 4 figures and 12 references, 9 of which are Soviet.

SOV/89-7-2-5/24

TITLE:

The Circulation System of a Nuclear Reactor as a Source of Radiation (Tsirkulyatsionnyy kontur yadernogo reaktora kak istochnik izlucheniya)

PERIODICAL: Atomnaya energiya, 1959, Vol 7, Nr 2, pp 129 - 137 (USSR)

ABSTRACT:

The task described in reference 1, i. e. consideration of a circulation loop containing one single isotope, as a radiation source and computing the strength of this source, was extended for such cases when several isotopes form in the substance to be activated and these isotopes have a series of radioactive decay products. The absolute maximum output of such a circulation system and the neutron consumption per output unit was theoretically calculated for the following elements: Na, Sc, Mn, Ga, Br, In, Sb, La, Ir which can be considered as materials to be activated in the circulation. It was found that In and its alloys can be best utilized. A circulation was separately examined in which the substance to be activated contained fissile isotopes (uranium circulation). It was proved that the specific capacity of this kind of circulation under the same conditions

Card 1/2

The Circulation System of a Nuclear Reactor  
as a Source of Radiation

SOV/89-7-2-5/24

is less than that of a circulation in which metal Indium or its alloys are being irradiated. As a special case they examined in an irradiation apparatus the uranium circulation of fuel not completely burned out in a reactor. The authors show that in this case the capacity can be increased 2-4 times in comparison with a device in which fully burned out fuel elements are used only once. The theoretically developed formulas for the specific capacity of circulations are separately derived in an annex. There are 3 figures, 2 tables, and 16 references, 6 of which are Soviet.

TITLE:

The Circulation Loop of a Nuclear Reactor as a Radiation Source, Especially for Radiation Chemistry ("Tsirkulyatsionnyy kontur yadernogo reaktora kak istochnik izlucheniya, v chastnosti dlya radiatsionnoy khimii")

PERIODICAL:

Atomnaya energiya, 1958, Vol 5, Nr 5, pp 533-541 (USSR)

ABSTRACT:

A substance to be activated is sent through a loop which passes through the reactor and is connected with a radiation chamber. The  $\gamma$ -radiation emitted by the substance is used in a radiation chamber (e.g. for radiation-chemical work). The problem to be solved is to determine by calculation the optimum duration of time during which the substance to be activated should remain in the reactor, in the radiation chamber, and in the connecting tubes. For this purpose it is necessary that with a given neutron flux, with given activation properties of the substances, and an assumed time of operation of the loop, the average energy of  $\gamma$ -radiation emitted per second in the radiation chamber per liter of the activated substance must be a maximum. The problem is solved

Card 1/3

SOV/89-5-4/27

The Circulation Loop of a Nuclear Reactor as a Radiation Source, Especially  
for Radiation Chemistry

only for an isotope, which is not a radioactive product produced during activation. The corresponding formulae and families of curves are given.

The calculation of a loop in which liquid indium circulates is particularly instructive. The neutron flux is assumed to be  $10^{13}$  n/cm<sup>2</sup>.sec, the volume to be activated in the reactor - 1 l, duration of the circulation of the loop - 50 days, length of connecting tubes - 20 m, the smallest permissible cross section in the connecting tubes - 0.5 cm<sup>2</sup>, with a maximum velocity of flow amounting to 0.1 m/sec. From these data it follows that the average energy of  $\gamma$ -radiation amounts to 2 700 W/l, which corresponds to a preparation with an activity of  $2.7 \cdot 10^5$  gram equivalent Ra in one liter.

In the case of optimum working conditions the energy of  $\gamma$ -radiation can be increased to 4 900 W/l.

Professor V. I. Veselovskiy gave general directives with respect to the investigations to be carried out, and results were discussed with V. L. Karpov.

The mathematical derivation of the principal formula is

TITLE: Absorption of  $\gamma$ -radiation in infinite systems

PERIODICAL: Zhurnal tekhnicheskoy fiziki, v. 31, no. 7, 1961, 837 - 842

TEXT: The energy distribution in space of  $\gamma$  quanta in a homogeneous, unbounded medium, the quanta being emitted by a point source, was investigated by B. V. Novozhilov (ZhETF, 33, no. 5, 1287, 1957) using diffusion-age approximation. This approximation is only applicable if the condition  $l \partial n / \partial s \ll n$  (1) is fulfilled.  $l$  is the mean free path of the quantum with the age  $t$ ;  $\partial n / \partial s$  is the density gradient of quanta with this age at the distance  $r$ . It is shown that with sufficiently small energies this condition is not fulfilled in the case of a point source. But if  $\gamma$  sources are uniformly distributed in an unbounded, homogeneous medium, the distribution function does not depend on the space coordinates and the directions of motion of the quanta. Thus, (1) is fulfilled and an age approximation can be used instead of a diffusion-age approximation. Thus the system of equations

Card 1/5

S/057/61/031/007/013/021  
B104/B206

Absorption of  $\gamma$ -radiation ...

$$\frac{dq(\tau)}{d\tau} = -x(\tau)q(\tau), \quad (2)$$

$$\tau(\lambda) = \frac{1}{S} \int d\lambda' [\mu_p(\lambda') \xi(\lambda')]^2,$$

$$x(\tau) = 3\mu_\phi(\lambda) \mu_k(\lambda) \xi(\lambda).$$

for the quanta density can be given.  $\{\lambda\}$  is the mean change of the wavelength of the  $\gamma$ -quanta due to Compton scattering,  $q(\tau)|_{\tau=0} = S\delta(\lambda - \lambda_0)$  the initial condition,  $S$  the power of the monoenergetic sources in quanta/cm<sup>3</sup>.sec;  $\lambda_0$  is the wavelength of the sources in Compton units ( $\lambda = mc^2/h\nu$ ;  $mc^2 = 0.51$  Mev;  $h\nu$  is the quantum energy in Mev);  $\mu_\phi(\lambda)$  and  $\mu_k(\lambda)$  are linear coefficients of the photoelectric effect and Compton process. The solution of (2) can be easily given by

$$q(\tau) = q(\lambda) = S \exp \left\{ - \int_{\lambda_0}^{\lambda} \frac{\mu_p(\lambda')}{\mu_p(\lambda') \xi(\lambda')} d\lambda' \right\} \quad (3)$$

Card 2/5

S/057/61/031/007/013/021  
B104/B206

Absorption of  $\gamma$ -radiation...

the  $\gamma$ -quanta flux can be expressed by

$$F(\lambda) = cn(\lambda) = \frac{S}{\mu_s(\lambda) \xi(\lambda)} \exp \left\{ - \int_1^\infty \frac{\mu_s(\lambda') d\lambda'}{\mu_s(\lambda') \xi(\lambda')} \right\}. \quad (5)$$

Comparisons with results by U. Fano et al. (J. Res. of NBS, 59, 3, 207, 1957) showed that the solution (5) conforms with that by Fano. The authors obtain

$$E_{\text{scattered}} = S \frac{\tau(h\nu_0)}{\mu(h\nu_0)} h\nu_0 + \int_{h\nu_0}^{\infty} \tau(\lambda) h\nu F(\lambda) d\lambda, \quad (7)$$

for the energy absorbed by the unit volume of an unlimited, homogeneous medium.  $F(\lambda)$  corresponds to (5);  $\tau(h\nu_0)$  is the energy transfer coefficient;  $\mu(h\nu_0)$  is the linear total attenuation factor of  $\gamma$  radiation. The first expression in (7) describes the absorption of the original radiation, the second that of the repeatedly scattered radiation. After a short discuss-

S/057/61/031/007/013/021  
B104/B206

Absorption of  $\gamma$ -radiation...

sion of the accuracy of (7), the authors deal with the main problem of their investigation. They study the absorption of  $\gamma$  radiation in complex systems consisting of radiation sources and irradiated volumes (e.g., a "tubular heat exchanger", where the tubes are the radiation sources). The authors investigated, as an example, the irradiator of an indium-gallium radiation cycle of the type "tubular heat exchanger". The volume concentration of the In-Ga alloy was 5%, that of the water 95%; the alloy contained 22 percent by volume In. The relative distribution of the  $\gamma$  radiation was determined. Under the assumption that the age approximation is applicable, it was possible to separate the energy absorbed in the alloy (source) from that absorbed in water (irradiator).

$$E_{\text{absor}} = S \left( \frac{\tau(h\nu_0)}{\mu(h\nu_0)} \right)_{\text{cmech}} h\nu_0 + \\ + S m c^3 \int_{h_0}^{h_{\text{max}}} \left[ \frac{\tau(\lambda)}{\lambda \mu_{\text{cmech}}(\lambda) \xi(\lambda)} \right]_{\text{cmech}} \exp \left\{ - \int_{h_0}^{\lambda} \left( \frac{\mu_{\text{cmech}}(\lambda')}{\mu_{\text{cmech}}(\lambda') \xi(\lambda')} \right)_{\text{cmech}} d\lambda' \right\} d\lambda. \quad (9)$$

was obtained, where for the respective component,  $\{\tau(\lambda)\}_{\text{CMECH}}$  must be

Card 4/5

S/057/61/031/007/013/021  
B104/B206

Absorption of  $\gamma$ -radiation...

replaced by  $\{\gamma(\lambda)\}_i$ . Calculations for various lines, for which the initial energies of the sources were assumed to be differently strong, showed that with energy reduction of the initial radiation, an all the greater part of the  $\gamma$  radiation energy is absorbed in the substance of the source. There are 1 figure and 10 references: 7 Soviet-bloc and 3 non-Soviet-bloc. The references to English-language publications read as follows: H. Goldstein et al., Final Report, No. 10, 5075. 1954; P. AUTHOR: Ryabukhov, S. I.

TITLE: Modifying cast iron by low-silicon or low-manganese magnesium alloys

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 1, 1962, 31, abstract 1V225  
(v sb. "Polucheniye izdeliy iz zhidk. met s uskoren. kristalli-  
zatsiyey". Moscow - Kiyev, Mashgiz, 1961, 140-146)

TEXT: Si-Mg alloys are used for obtaining cast iron modified with magnesium. According to the present methods of production their Si content is > 40%. To obtain mechanically strong and chemically homogeneous Mg-cast iron it is necessary to have an alloy with Si content  $\leq 20\%$ . For this purpose lean Fe-Si is used in producing the alloy. However, with such a Fe-Si the solubility of the Mg and the formation of the required  $Mg_2Si$  is sharply decreased. In order to raise the solubility, the author proposes to carry on the mixing of Mg with Fe-Si in a hermetically closed lined revolving drum. The inner space of the drum is divided into two sections by a lined partition whose height exceeds the drum radius. Mg and cryolite are placed in one section. The drum together with its contents is heated by mazut or gas up to 700°C. Then Fe-Si is poured into the

Card 1/2

A060/A101

Modifying cast iron by low-silicon ...

other section, the drum is hermetically closed and set into rotation. The heat of the Fe-Si melts the magnesium makes it mix partially with the former, and a certain part is evaporated. As the temperature decreases, the alloy obtained crystallizes. The remaining alloy is broken out of the drum and broken into pieces by hammer. The optimum smelting conditions are: Fe-Si 350kg, Mg 40 kg, cryolite 10 kg, the temperature of the Fe-Si 1,360°C, rotation of the drum for 60 min at a rate of 30 rpm. The alloy contains 18% Si and 10% Mg. At the present time work is being conducted on obtaining heavy Mg-alloy with 10% Mg and 20% Mn content. The specific weight of this alloy will exceed that of the cast iron and therefore it will be possible to utilize it without any special accessories for immersion in the crude iron.

Mr. I. Dugotankova, and L. V. Shechetina.

Purpose. This book is intended for the technical personnel of foundries. It may be used by students of the field.

Content. This collection of articles discusses problems in foundry procedures. Individual articles treat the melting of metals and their alloys, mechanization and automation of casting processes, aspects of the manufacture of steel, cast iron, and various metal castings. No personal names are mentioned. References accompany individual articles.

Treating cast iron with magnesium in a pear-shaped ladle.  
S. I. Ryabukhov. Zaishay Protsess 1956, No. 3, 26.—  
In the lining of the bottom of a vessel resembling an eccentric Bessemer converter is provided a chamber in which Mg is placed. When the converter is in a horizontal position, this chamber is on the top and is connected with the melting space of the vessel, with a slot. When the converter is tilted, Mg vaporizes and escapes through this slot into the molten bath. An excessively large slot causes explosions and a too-narrow one fails to melt. J. D. Cat

Treatment of Cast Iron with Magnesium in a Pear-Shape Ladle. S. I. Ryabukhov. (Zakhar Prokof'ev, 1956, (3), 26). [In Russian]. Experiments are briefly described in which the influence of various factors on the inoculation of cast iron with Mg were studied with the aid of a special 100-kg ladle. This was roughly the shape of a converter and was filled in the horizontal position. On tilting the ladle the iron found its way via a slit to a small chamber containing the magnesium. 1600 sq. mm was found to be the optimal cross-sectional area for the slit; a larger value leading to splashing and a lower value to quick erosion of the slit, although accompanied by more efficient inoculation. — RY

(Vozmozhnyye varianty obrabotki chuguna magniyem)

PERIODICAL: V sb.: Novoye v liteyn. proiz-vye. Nr 2. Gor'kiy, Knigoizdat,  
1957, pp 116-123

ABSTRACT: Tests were made of methods for treating cast iron (CI) by means of powdered Mg blown through in a jet of N<sub>2</sub> and by introducing a Mg rod or Mg vapors. An industrial installation was designed for the production of Mg powder, as well as a special dipper device for blowing the powder by means of N<sub>2</sub> through the CI. Data are given for: a) The determination of the pressure of Mg needed for the blowing process; b) The adaptation of Mg 4; c) The amount of the residual Mg in the CI in accordance with the duration of the blowing process. It was found that the temperature of the CI was considerably lowered by the passage of large amounts of cold N<sub>2</sub> through it. The original installation for the vaporization of Mg and for the passage of its vapors through molten CI is described.

Equipment for introducing magnesium into cast iron  
S. I. Ryabukhov. *Litelnoe Pravosudstvo* 1957, No. 5, 14-  
16; cl. C.I. 50, 8422f.—A vessel similar to the side-blown  
Bessemer converter is mounted on trunnions near its center  
of gravity and is provided with a chamber near its bottom in  
the top right-hand corner when brought in a horizontal pos-  
ition, thus being above the level of molten iron. This  
chamber is filled with Mg before pouring in the iron, after  
which the vessel is straightened and Mg is allowed to react.

lies, product quality, technical and economic indicators of the process are taken in consideration. It is shown that the most efficient is the method of oxo synthesis utilizing thermal cracking gasoline distillates and paraffin-cracking products. The alcohols produced by this procedure can be used in the manufacture of polyvinyl chloride items (frost resistance to -30°). Of promising nature is the production of I from II, with the view of utilizing the plasticizer in items having a frost resistance from -40 to -50°. See RZhKhim, 1962, 13L19. Yu.P.

Title : Movable installations of power capacitors

Periodical : Energetik, 6, 26-27, Je 1955

Abstract : A major work was done at the establishments of the Karaganda Coal Combine in order to raise the power factor. The basic measure consisted in introducing synchronous motors in ventilating and compressor installations and also synchronous converters and static capacitors at the central substations of the combine. The author describes the details of these installations. Three diagrams, one table.
